IN EQUATIONS

First Step: STFT

$$X_m(k) = \sum_{n=-\infty}^{\infty} h(mM - n)x(n)W_{l_1}^{kn},$$
$$k = 0, \dots, l_1 - 1,$$

where:

- l_1 denotes the number of frequency bins in the acoustic frequency axis,
- $W_{l_1} = \exp(-j\pi/l_1)$,
- M is the shift parameter (or, hop size) in the computation of the STFT,
- $h(n)$ is the acoustic frequency analysis window.

IN EQUATIONS

Second Step: Modulation frequencies estimation of the Subband Envelopes

$$X_l(k, i) = \sum_{m=-\infty}^{\infty} g(lL - m) |X_m(k)| W_{l_2}^{im},$$
$$i = 0, \dots, l_2 - 1,$$

where:

- l_2 is the number of frequency bins along the modulation frequency axis,
- $W_{l_2} = \exp(-j(f_M/F_s) \pi/l_2)$,
- f_M and F_s denoting the maximum modulation frequency we search for, and the sampling frequency, respectively,
- L is the shift parameter of the second STFT, and
- $g(m)$ is the modulation frequency analysis window.

DIMENSIONALITY REDUCTION, HO-SVD

- 1 Create tensors: $\mathcal{D} \in R^{l_1 \times l_2 \times l_3}$
- 2 Decompose of tensor \mathcal{D} to its n -mode singular vectors:

$$\mathcal{D} = \mathcal{S} \times_1 U_{af} \times_2 U_{mf} \times_3 U_{samples}$$

where \mathcal{S} and U are referred to as *core tensor* and *unitary matrix*, respectively and \times_n denotes the n -mode product.

- 3 Rank the n -mode singular values
- 4 Near-optimal projections (PCs): truncate Singular Matrices so that we keep $a\%$ “energy” of \mathcal{D}

n -mode singular vectors:

- Let consider tensor $\mathcal{D} \in R^{l_1 \times l_2 \times l_3}$
- Unfold \mathcal{D} to $\mathbf{D}_{(n)}$:
 - ① $l_1 \times l_2 l_3$ matrix $\mathbf{D}_{(1)}$
 - ② $l_2 \times l_3 l_1$ matrix $\mathbf{D}_{(2)}$
 - ③ $l_3 \times l_1 l_2$ matrix $\mathbf{D}_{(3)}$

The n -mode singular values and vectors: SVD of $\mathbf{D}_{(n)}$.

DEFINITION (UNITARY MATRIX)

An $(I_n \times I_n)$ unitary matrix $\mathbf{U}^{(n)}$, $n = 1, 2, 3$, contains the n -mode singular vectors (SVs):

$$\mathbf{U}^{(n)} = \begin{bmatrix} U_1^{(n)} & U_2^{(n)} & \dots & U_{I_n}^{(n)} \end{bmatrix}. \quad (1)$$

Each matrix $\mathbf{U}^{(n)}$ can directly be obtained as the matrix of left singular vectors of the “matrix unfolding” $\mathbf{D}_{(n)}$ of \mathcal{D} along the corresponding mode.

DIMENSIONALITY REDUCTION, HO-SVD

$$\mathcal{D} = \mathcal{S} \times_1 U_{af} \times_2 U_{mf} \times_3 U_{samples}$$

- \mathcal{S} is referred to as core tensor (same dimensions as \mathcal{D})
- $\mathbf{U}_{af} \in \mathbb{R}^{l_1 \times l_1}$, is the unitary matrix of the acoustic frequency subspace.
- $\mathbf{U}_{mf} \in \mathbb{R}^{l_2 \times l_2}$, is the unitary matrix of the modulation frequency subspace.
- $\mathbf{U}_s \in \mathbb{R}^{l_3 \times l_3}$ is the samples subspace matrix.
- \times_n denotes n -mode product.

DIMENSIONALITY REDUCTION, HO-SVD

Defining n-product $\mathcal{S} \times_n \mathbf{U}^{(n)}$:

- $\mathcal{S} \in \mathbb{R}^{l_1 \times l_2 \times l_3}$
- $\mathbf{U}^{(n)} \in \mathbb{R}^{l_n \times l_n}$
- Example; for $n = 2$ this is an $(l_1 \times l_2 \times l_3)$ tensor given by

$$\left(\mathcal{S} \times_2 \mathbf{U}^{(2)} \right)_{i_1 i_2 i_3} \stackrel{\text{def}}{=} \sum_{i_2=1}^{l_2} s_{i_1 i_2 i_3} u_{i_2 i_2}.$$

References

- 1 Create tensors: $\mathcal{D} \in R^{l_1 \times l_2 \times l_3}$ and decompose it to its n -mode singular vectors:

$$\mathcal{D} = \mathcal{S} \times_1 U_{af} \times_2 U_{mf} \times_3 U_{samples}$$

- 2 Rank the n -mode singular values
- 3 Near-optimal projections (PCs): truncate Singular Matrices so that we keep $a\%$ “energy” of \mathcal{D}

DIMENSIONALITY REDUCTION, HO-SVD

- Contribution of the j^{th} n -mode singular vector $U_j^{(n)}$:

$$\alpha_{n,j} = \lambda_{n,j} / \sum_{j=1}^{I_n} \lambda_{n,j}$$

where $\lambda_{n,j}$ is the corresponding singular value

- Put a threshold on $\alpha_{n,j}$ and retain the R_n ($n = 1, 2$) singular vectors
- Truncate matrices: $\hat{\mathbf{U}}^{(1)} \equiv \hat{\mathbf{U}}_{af} \in \mathbb{R}^{I_1 \times R_1}$ and $\hat{\mathbf{U}}^{(2)} \equiv \hat{\mathbf{U}}_{mf} \in \mathbb{R}^{I_2 \times R_2}$
- Project new MS data on to the truncated matrices:

$$\mathbf{Z} = \hat{\mathbf{U}}_{af}^T \mathbf{B} \hat{\mathbf{U}}_{mf}$$

where $\mathbf{B} \equiv |X_l(k, i)| \in \mathbb{R}^{I_1 \times I_2}$ and $\mathbf{Z} \in \mathbb{R}^{R_1 \times R_2}$

Mutual Information between two random variables x_i and x_j is defined as:

$$I(x_i; x_j) = \int dx_i \int dx_j P_{ij}(x_i, x_j) \log_2 \left[\frac{P_{ij}(x_i, x_j)}{P_i(x_i)P_j(x_j)} \right]$$

where

- $P_{ij}(x_i, x_j)$ denotes the joint probability density function (pdf)
- $P_i(x_i)$ and $P_j(x_j)$ denote the marginal pdfs

Use of an AM-FM decomposition algorithm based on the adaptive time-varying quasi-harmonic model for speech.

- High resolution in Time-Frequency plane.
- Estimation of Vocal Tremor for any sinusoidal component of speech.
- Time dependent Vocal Tremor estimations.

AM-FM DECOMPOSITION USING AQHM

- Speech is modeled as a sum of AM-FM sinusoids:

$$s(t) = \sum_{k=1}^K a_k(t) \cos(\phi_k(t))$$

- K is the number of components,
 - $a_k(t)$ is the instantaneous amplitude of the k^{th} sinusoid,
 - $\phi_k(t)$ is the instantaneous phase of the k^{th} sinusoid, and
 - $f_k(t) = \frac{1}{2\pi} \frac{d\phi_k(t)}{dt}$ is the instantaneous frequency of the k^{th} sinusoid.
- AM-FM decomposition algorithm tries to estimate the instantaneous components.

PREPROCESSING OF INST. COMPONENT

- Downsample inst. component to $f_s = 1000\text{Hz}$
- Remove the very slow ($< 2\text{Hz}$) modulations of the instantaneous component.
- This is performed by Savinzy-Golay smoothing filter.
 - S-G smoothing filter performs a local polynomial regression.
 - S-G filter parameters: 4th order polynomial & 1sec frame size.
 - Advantage: Preserve features of the time-series such as relative maxima, minima and width.

COMPUTE MODULATION FREQUENCY & LEVEL

- Assuming that the processed inst. component has a single but time-varying modulation frequency and modulation level.

$$x(t) = m(t)\cos(\psi(t))$$

- Apply for second time the AM-FM dec. alg. to the processed inst. component.
- Thus,
 - Modulation frequency, $\frac{1}{2\pi} \frac{d\psi(t)}{dt}$, is estimated from the FM component of AM-FM dec. alg.
 - Modulation level, $m(t)$, is estimated from the respective AM component.

References

- Estimating vocal tremor attributes:
 - extract instantaneous frequency and instantaneous amplitude.
- Comparing vocal tremor attributes before and after vocal loading:
 - compare the modulation frequencies and the modulation levels of two voiced signals of the same speaker before and after vocal loading.

DEFINITIONS

- Vocal Loading Amplitude Indicator (VLAI) = Mean modulation level after loading - Mean modulation level before loading.
- Vocal Loading Frequency Indicator (VLFI) = Mean modulation frequency after loading - Mean modulation frequency before loading.
 - positive value: increase of vocal tremor attributes \Rightarrow possible degradation of voice.
 - negative value: decrease of vocal tremor attributes \Rightarrow possible enhancement of voice.
